Appendix F. Index relationship to site characteristics

Background:

The Vermont Department of Environmental Conservation (VT DEC) Wetland Bioassessment Program uses the VT Natural Heritage Inventory's Natural Community Classification System. This allows assessment of plant community integrity along a disturbance gradient that accounts for natural community characteristics. For example, condition comparisons should be made between one black spruce bog and another black spruce bog, or between one wet clayplain forest to another wet clayplain forest.

This project evaluates the validity of the classification system in the context of assessment tools. The steps taken to address the evaluation included calculation of plant community metrics and comparison of metric values in least-disturbed reference sites among site classes. The site classification system can be simplified to recognize similarities among classes and to allow development of assessment tools. Combining similar classes, with similar reference metric distributions, can result in precise reference condition characteristics and robust metric responses for assessment. This also reduces unnecessary complexity in classification.

Survey Types

VT DEC recorded data from several survey types. We explored data characteristics to determine which types would be applicable for the intended analyses. We pursued data sets that had plentiful samples, similar effort (measured as plant richness), and quantitative measures (% cover). After reviewing the 10 survey types in the data set, we decided to use three data sets that met these criteria: Heritage, Wetlands Heritage, and Wetlands Transect (Figure 1). We considered Heritage Transect, but richness was consistently lower than the others. The Species List data set had several samples, but did not quantify coverage. We can revisit other types after initial analysis.

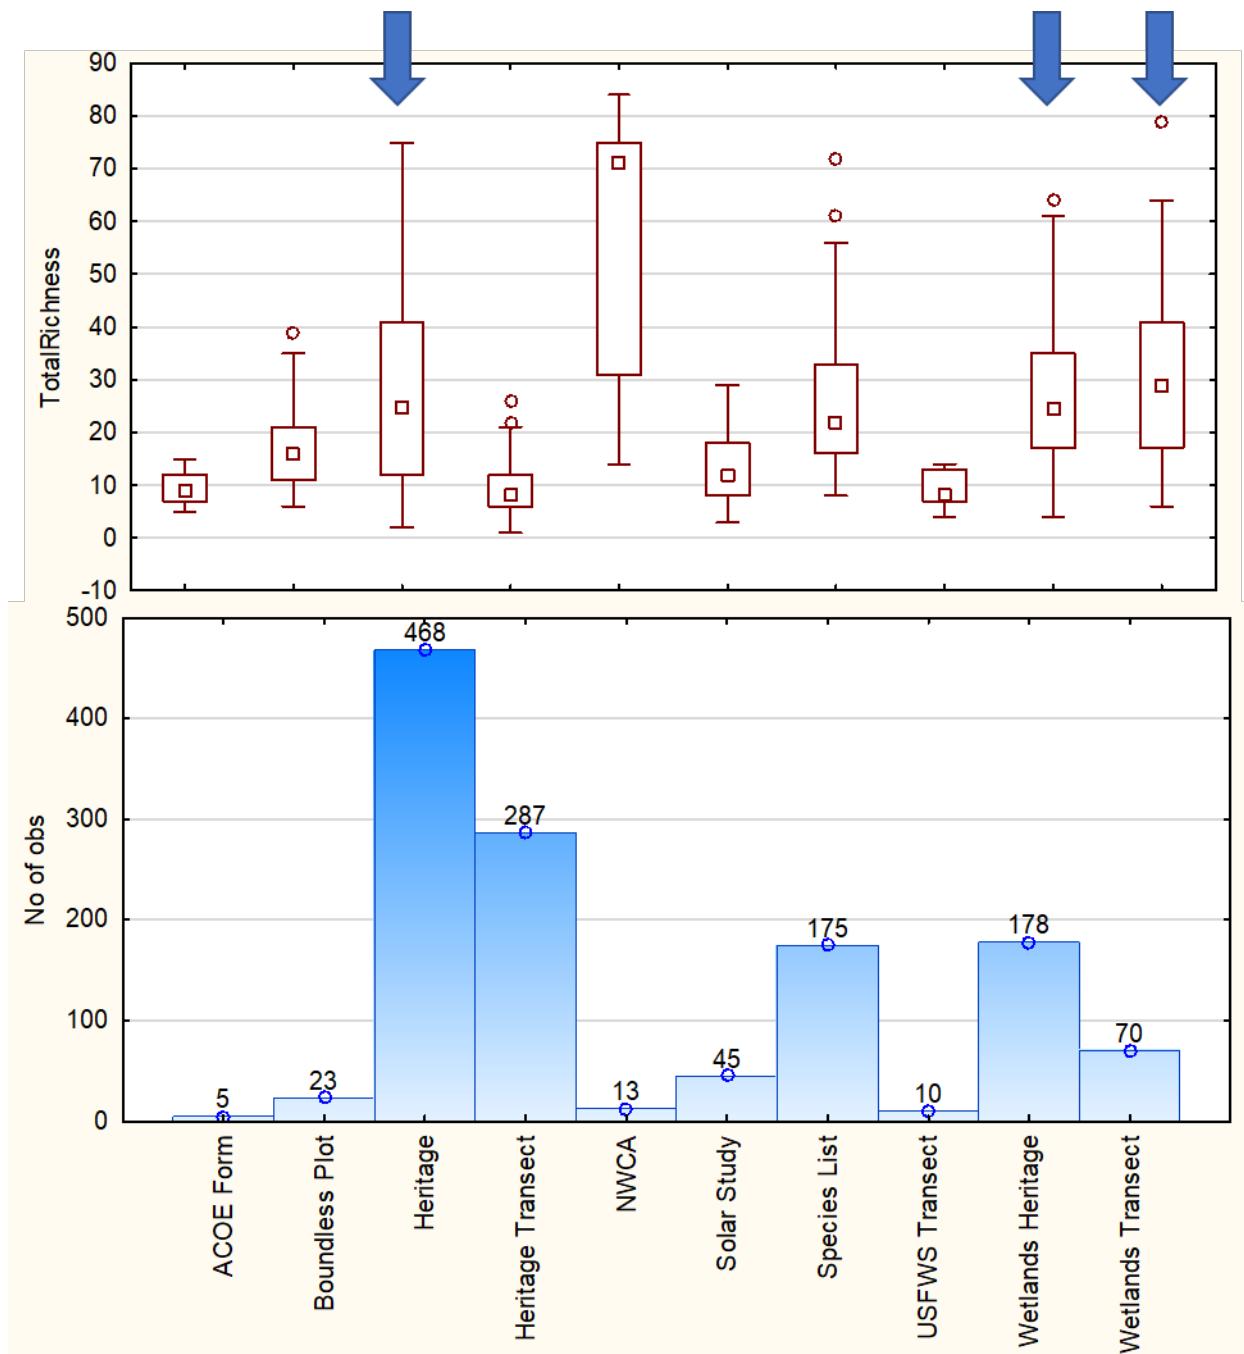

Figure 1. Plant species richness and number of samples for 10 survey types in the VT DEC database.

Site Disturbance Designations

VT DEC identified sites that they considered to be relatively undisturbed reference. The designation considered certain aspects of the Vermont Rapid Assessment Method (VRAM) assessments. VT DEC recommended that all Heritage sites should be considered reference unless

otherwise marked in the data set. Sites without existing designations by VT DEC and not Heritage were designated as ‘ambiguous’, meaning that there was uncertainty about the site disturbance conditions. After applying these designations, most reference sites were from the Heritage survey type (Table 1).

Table 1. Wetland site counts by disturbance designation and survey type.

Survey Type	Reference	Ambiguous	High Disturbance
Heritage	450	11	7
Wetlands Heritage	55	64	59
Wetlands Transect	1	64	5

Metric Calculations

The survey data included two data tables that were used in metric calculations. The first table included site/sample identifiers, plant species, and species enumeration. The second table included several characteristics of each species (traits). The traits designated a Coefficient of Conservatism (CoC, general tolerance to stressors), wetness affinity, native status, and monocotyledon division. Most traits were assigned by VT DEC, though Tetra Tech completed some incomplete ‘Native’ entries based on information from the Native Plant Trust¹. Most metrics were counts of species, percentages by trait, or weighted average of trait values (Table 2).

Table 2. Wetland metric descriptions that were tested in the analysis. Continued on the following page.

Metric Abbreviation	Metric Description
TotalRichness	The total number of vascular plant taxa in the sample list
nt_Native	The number of native vascular plant taxa (using the "Native" field in the "Species Biocriteria Index" database table)
nt_NativeMonocot	The number of native and monocot vascular plant taxa (Monocot designation from NWCA2011_planttaxa.csv downloaded from the EPA NARS website)
nt_Senstv710	The number of vascular plant taxa with "Art CoC" designations of 7 - 10
nt_Toler04	The number of vascular plant taxa with "Art CoC" designations of 0 - 4 (includes non-natives, excludes taxa without designations)
nt_WetOblig35	The number of vascular plant taxa with "ACOE Wetness" designations of 3 - 5
nt_WetUpl-5-3	The number of vascular plant taxa with "ACOE Wetness" designations of -5 - -3
pt_Native	The percent of all native vascular plant taxa (using the "Native" field in the "Species Biocriteria Index" database table)
pt_NatvMonocot	The percent of all native and monocot vascular plant taxa (Monocot designation From nwca2011_planttaxa.csv downloaded from the EPA NARS website)
pt_Senstv710	The percent of all vascular plant taxa with "Art CoC" designations of 7 - 10
pt_Toler04	The percent of all vascular plant taxa with "Art CoC" designations of 0 - 4 (includes non-natives, excludes taxa without designations)
pt_WetOblig35	The percent of all vascular plant taxa with "ACOE Wetness" designations of 3 - 5
pt_WetUpl-5-3	The percent of all vascular plant taxa with "ACOE Wetness" designations of -5 - -3
SumOfTotalCover	Sum of "Cover" of vascular plants in the "Plot_Data" database table
pc_Native	Percent of total "Cover" of native vascular plants in the "Plot_Data" database table
pc_NatvMonocot	Percent of total "Cover" of native monocot plants in the "Plot_Data" database table
pc_Senstv710	Percent of total "Cover" of vascular plants with "Art CoC" designations of 7 - 10
pc_Toler04	Percent of total "Cover" of vascular plants with "Art CoC" designations of 0 - 4 (includes non-natives, excludes taxa without designations)
pc_WetOblig35	Percent of total "Cover" of vascular plants with "ACOE Wetness" designations of 3 - 5
pc_WetUpl-5-3	Percent of total "Cover" of vascular plants with "ACOE Wetness" designations of -5 - -3
RelImpNative	Relative importance of native taxa, calculated as $([pc_Native]+[pt_Native])/2$

RelImpSenstv710	Relative importance of sensitive taxa, calculated as ([pc_Native]+[pt_Native])/2
wac_tolerance	Average CoC weighted by vascular plant cover
Cover_Weighted_CoC	Series of Queries by CH: Cover_Weighted_CoC: [Qry_CoverWgtCoC2]![SumOfCoverCoC]/[Qry_CoverWgtCoC2]![AvgOfSumOfCover]
wat_tolerance	Average CoC by vascular plant taxa
FQAI	FQAI: Sum([Art CoC])/([TotSpecies_PositiveCounts]^0.5); (as described by Magee 2019 for the VMMI) (taxa without Art Coc designation are interpreted as non-native 0)
FQI	FQI: Avg([Art CoC])*([TotSpecies_including0count]^0.5)
FQI_weighted	FQI_weighted: Avg([Art CoC]*[TotalCover])*([TotSpecies_including0count]^0.5)
VMMI	Calculated from 4 metrics, per Vegetation Multi-Metric Index (VMMI) Magee et al.(2020); FQAI, RelImpNative, nt_Toler04, pc_NatvMonocot
Hprime	Shannon-Wiener index (base 2) (diversity index based on both % cover and taxa richness): $H' = -\sum(((Cover)/[SumOfTotalCover]) * \log([Cover]/[SumOfTotalCover]))/\log(2))$

Data Pooling

Analysis could continue for each separate data set or for a combination of data sets. We tested opportunities for pooling the data sets by comparing metric distributions among data sets, concentrating on the reference sites. This was first done through visual inspection of box plots. Distributions with substantial overlap of interquartile ranges, especially in reference sites, indicated that the survey type was not affecting the metric values and that data sets might be pooled for analysis. The same types of metric plots were used to estimate metric sensitivity among disturbance categories. Several metrics had similar reference metric distributions (Figures 2 and 3, and Appendix A).

Wetland Metrics in Vermont

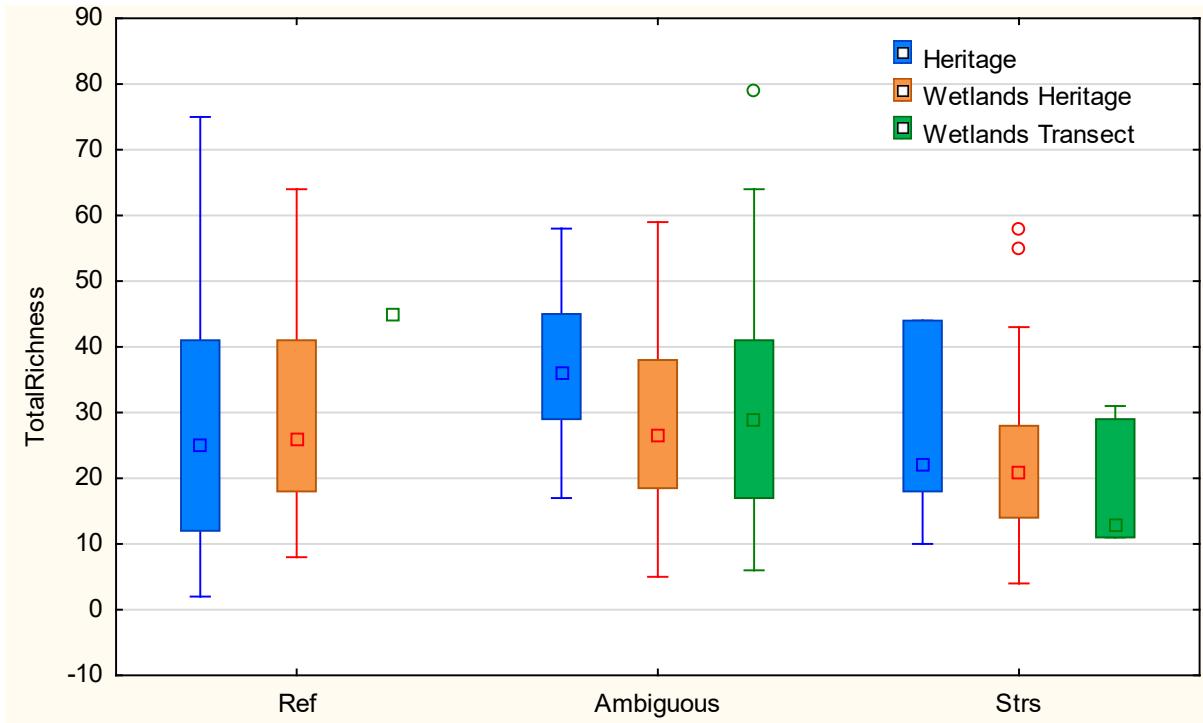

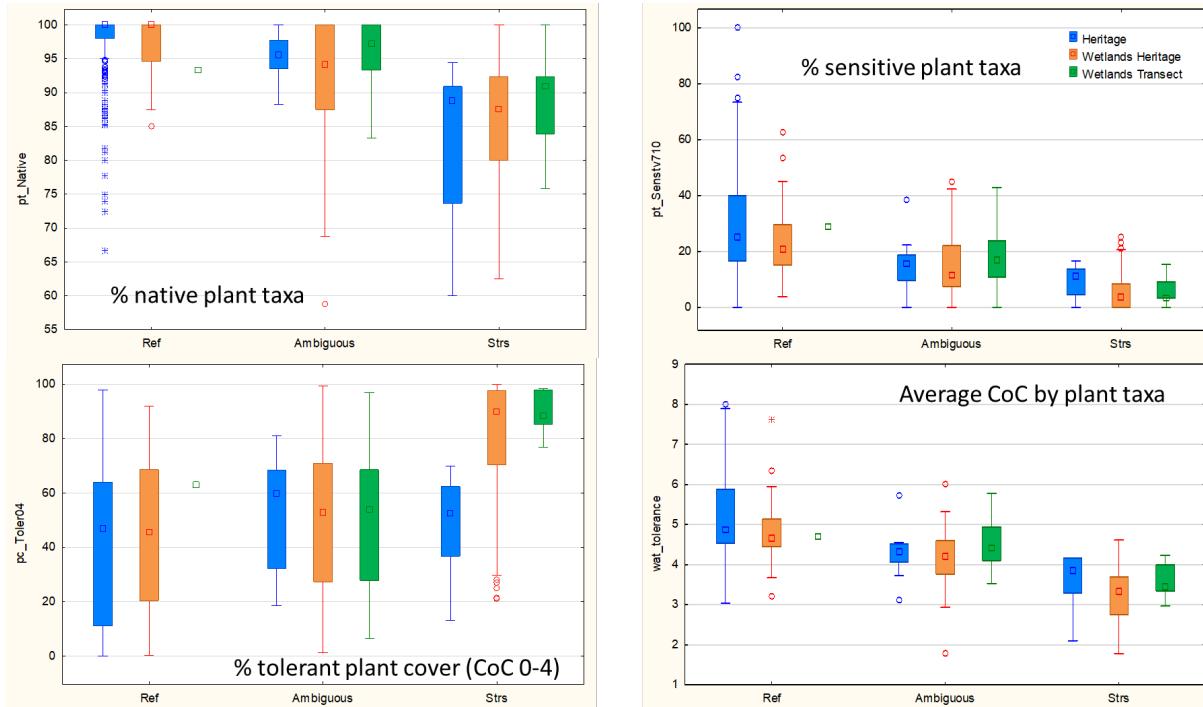

Figure 2. Distribution of Total Richness metric values among data sets and disturbance categories. Boxes represent interquartile ranges, whiskers are non-outlier range, and central marker is the median.

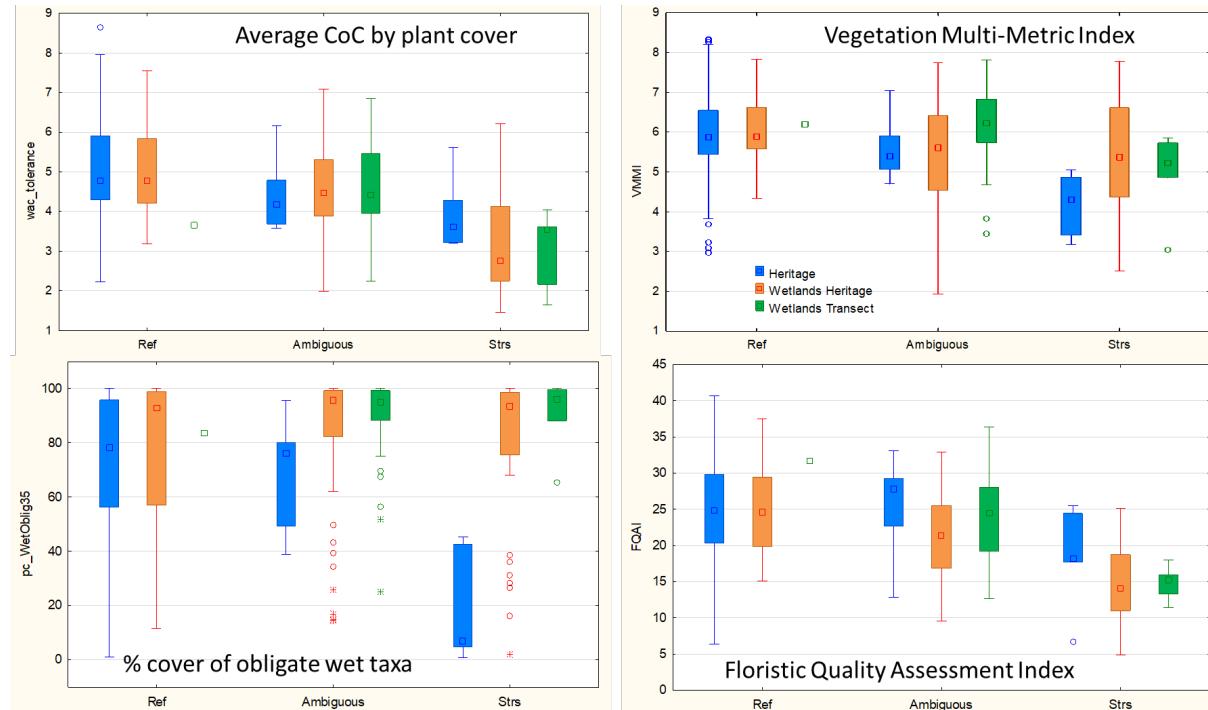

Figure 3. Distribution of a selection of metric values among data sets and disturbance categories. Boxes represent interquartile ranges, whiskers are non-outlier range, and central marker is the median.

We also tested reference metric distributions between the Heritage and Wetlands Heritage programs using a t-test. The single reference Wetland Transect site was not included. Heritage and Wetland Heritage reference sites have similar distributions in all but three metrics based on p values > 0.05 (Table 3). The disparate metrics can be avoided for assessments (number of native monocot taxa, number of obligate wetland taxa, and the weighted FQI). We assumed that the Wetland Transect survey data could be pooled based on similar distributions in ambiguous disturbance sites (visual interpretation of metrics).

Wetland Metrics in Vermont

Table 3. Results of t-tests of reference metric distributions among Heritage and Wetlands Heritage surveys.

Classification Schemes

VT DEC has associated wetland sites with several classification schemes.

Heritage Crossover:

Heritage Crossover wetland types are varied and specific. The specific types can be grouped into more general categories by descriptive label. The natural communities used are described in <https://vtfishandwildlife.com/wetland-woodland-wildland>. These represent relatively undisturbed ecosystems. Mapping units for more disturbed wetlands have been designated by VT DEC.

Wetlands Formation:

Wetlands Formation wetland types are varied and specific. The specific types can be grouped into more general categories by descriptive label. The Wetland Formation classes were generally aligned with, though more refined than, the Cowardin classes.

Cowardin Class:

Because the Cowardin classes were designated by a nested code instead of narrative label, it was possible to simplify and group the *basic* Cowardin classes:

- FO = Forested
- SS = Shrub/Scrub
- EM = Emergent

Classifications Evident in VT Wetlands

Based on the analysis of metric distributions in reference sites, the Heritage, Wetland Heritage, and Wetland Transect survey sites were pooled for an analysis of a classification scheme for Vermont wetlands. We explored metric discrimination among disturbance categories in all sites and in various wetland classes to determine the feasibility of selecting a functional classification scheme. For simplicity of grouping, we first checked the basic Cowardin classes; FO = Forested, SS = Shrub/Scrub, and EM = Emergent. Several metrics showed discernable responses to the disturbance categories and the wetland types (Figure 4). All but four metrics had different reference distributions in at least one of the Cowardin classes (ANOVA $p < 0.05$, Table 4). There were some differences among habitat and water quality variables among Cowardin classes and disturbance categories (Figure 5).

Table 4. ANOVA statistics for comparisons of reference distributions among Forested, Shrub/Scrub, and Emergent Cowardin wetland classes.

Wetland Metrics in Vermont

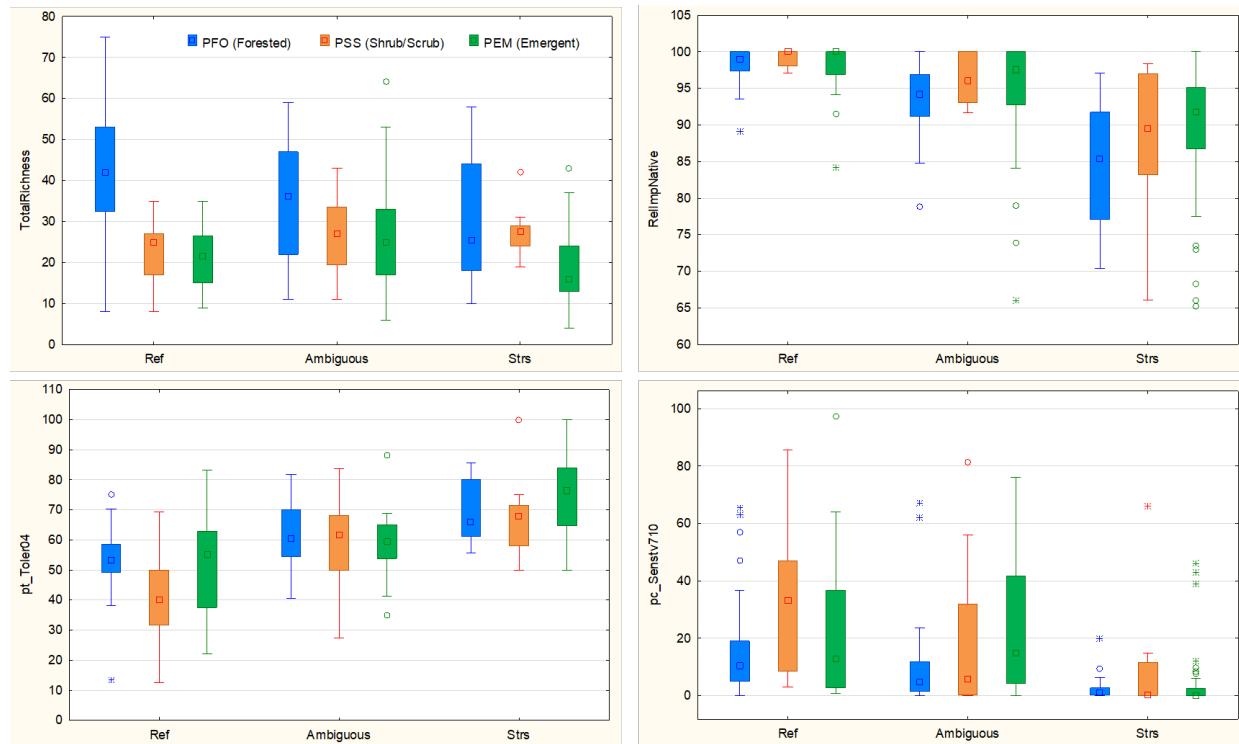

Figure 4. Selected metric distributions by disturbance category and Cowardin wetland class, showing total plant richness, relative importance of native species, percent tolerant taxa, and percent sensitive cover.

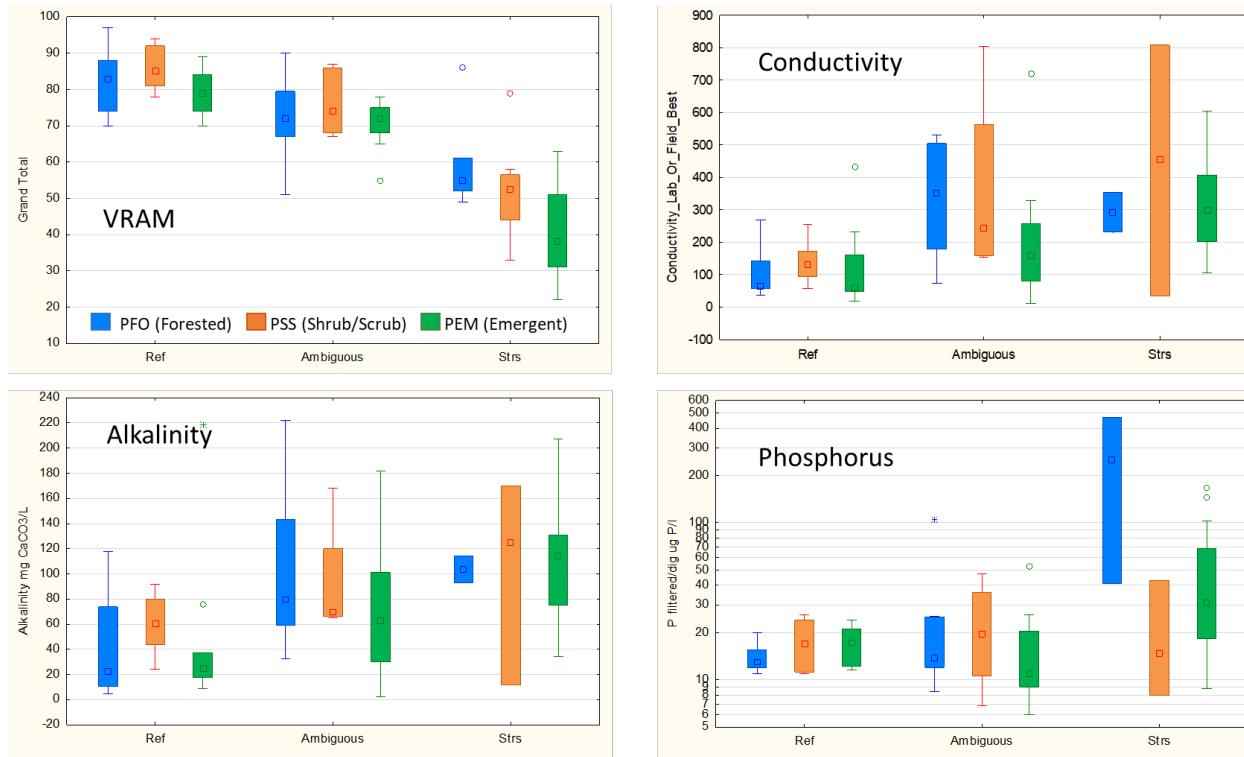

Figure 5. Distributions of Vermont Rapid Assessment Method (VRAM) and water quality variables among disturbance categories and Cowardin wetland classes.

After seeing that there were differences among reference metrics in Cowardin classes, we explored other classification schemes to determine the most reliable classification system. Explorations included examination of potential classes using metric distributions in and plots of plant community similarity in non-metric multidimensional scaling (NMS) of taxa presence. Heritage Crossover and Wetlands Formation wetland types are too varied (too many distinct classes) for simple classification. These might be simplified by grouping similar classes that had similar metric distributions or plotted in close proximity in the NMS diagrams. A final consideration for selecting a classification scheme included examination of metric discrimination of disturbance categories among potential classes.

With 504 reference sites, Cowardin classes give a strong signal of natural taxa composition in the NMS diagram (Figure 6). However, other wetland type grouping based on combinations of Heritage Crossover classes also showed distinction among reference wetland communities. There were 40 Wetland Crossover types that were plotted in reference site NMS diagrams. In successive experimental combinations of groupings for wetland types that plotted together in the ordinations, a preliminary classification scheme was developed and scrutinized for further refinement (Figure 7, Table 5).

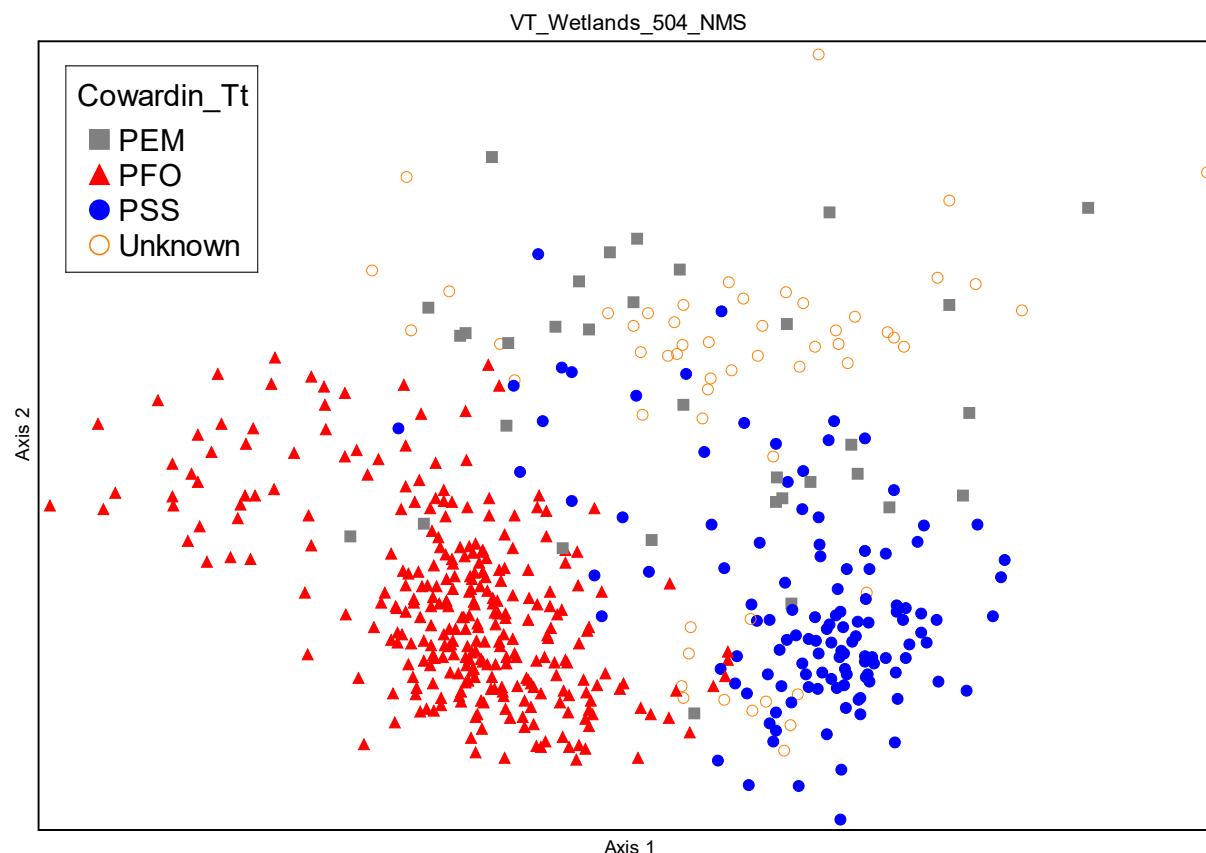

Figure 6. NMS diagram of reference wetland plant communities in Cowardin classes.

Table 5. Preliminary wetland class groupings based on combinations of Heritage Crossover wetland types. Continued on the following page.

Heritage Crossover Group	Heritage Crossover (Cowardin) Class	# Ref Sites
Beaver Wetland	Beaver Wetland (FO, SS, EM)	12
	Dwarf Shrub Bog (SS)	33
Bog, Poor Fen	Pitch Pine Woodland Bog	3
	Poor Fen (SS)	76
Intermediate, Rich Fen	Intermediate Fen (EM)	16
	Rich Fen (EM)	38
	Lakeside Floodplain Forest (FO)	4
Floodplain	Silver Maple-Ostrich Fern Riverine Floodplain Forest (FO)	13
	Silver Maple-Sensitive Fern Riverine Floodplain Forest (FO)	3
	Sugar Maple Floodplain Forest (FO)	19
	Wet Clayplain Forest (FO)	2
Maple, Cedar Swamp	Boreal Cedar-Sphagnum Basin Swamp (FO)	15

	Calcareous Red Maple-Tamarack Swamp (FO, SS)	15
	Hemlock-Balsam Fir-Black Ash Seepage Swamp (FO, EM)	33
	Hemlock-Northern White Cedar Swamp (FO)	1
	Hemlock-Sphagnum Acidic Basin Swamp (FO)	3
	Maple-Green Ash Swamp (FO)	12

	Red Maple-White Pine-Huckleberry Swamp (FO)	3
	Wet Sand-Over-Clay Forest (FO)	3
Spruce Swamp	Black Spruce Swamp (FO)	9
	Black Spruce Woodland Bog (FO, SS, EM)	11
	Lowland Spruce-Fir Forest (FO)	1
	Red Spruce-Cinnamon Fern Swamp (FO)	12
	Spruce-Fir-Tamarack Swamp (FO)	12
Seep	Northern Hardwood Seepage Forest (FO)	2
	Woodland Seep (FO, EM)	6
Other	Alder Swamp (SS)	3
	Alluvial Shrub Swamp (SS)	1
	River Cobble Shore	3
	Rivershore Grassland	1
	Sedge Meadow (EM)	4
	Shallow Emergent Marsh (EM)	1
	Sweet Gale Shoreline Swamp (SS)	3
	Unrecorded	3
	Wild Rice Marsh (EM)	1

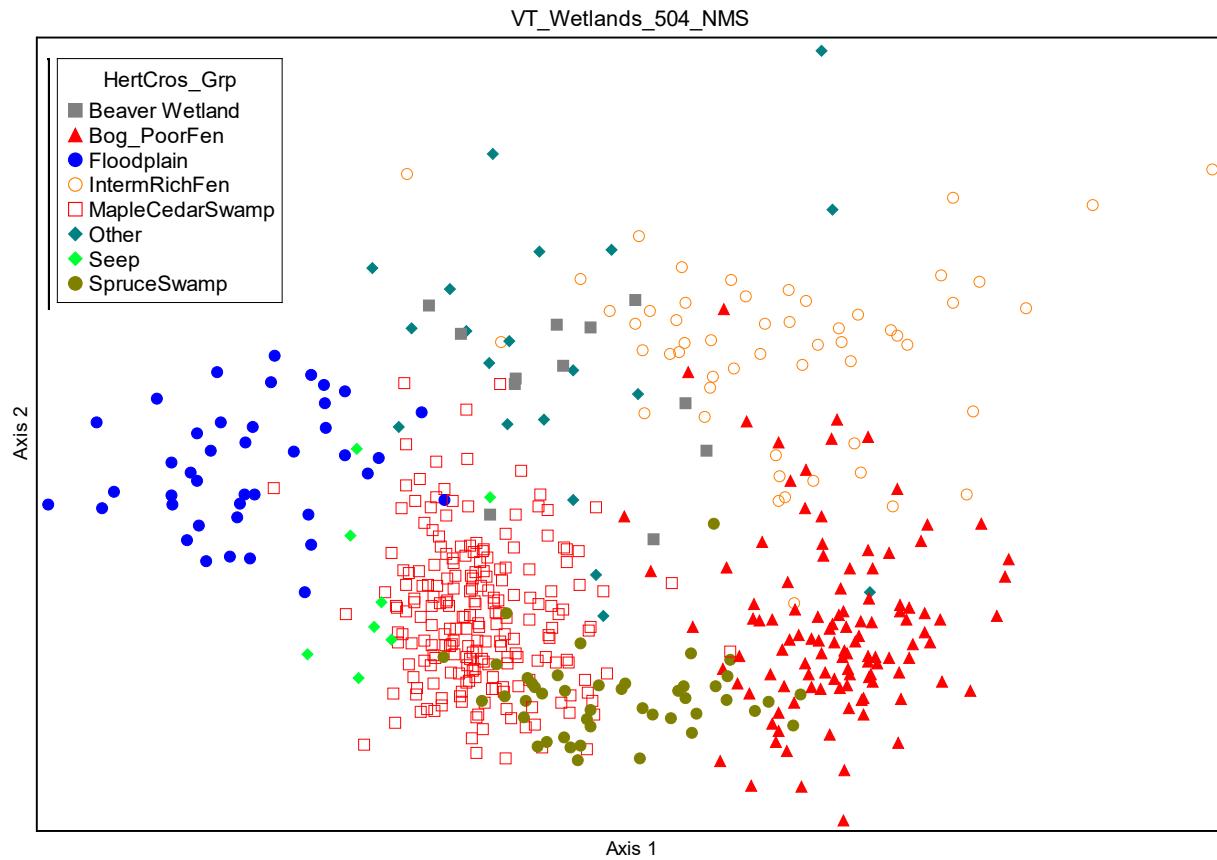

Figure 7. NMS diagram of reference wetland plant communities in preliminary wetland class groupings.

After reviewing selected metric distributions (Figure 8, Appendix B), additional class combinations became apparent. Metric distributions were similar for successively grouped metrics categories: Maple, Cedar Swamp + Seep; Intermediate Rich Fen + Bog, Poor Fen; and Beaver Wetland + Other. This resulted in five wetland classes proposed for continued analysis, as follows:

- Maple, Cedar Swamp + Seep
- Spruce Swamp
- Floodplain
- Intermediate Rich Fen + Bog, Poor Fen
- Beaver Wetland + Other

These classes showed good internal similarity in reference taxa composition (Figure 9), distinction of metric distributions among classes, good metric discrimination with stressed sites (Appendix C), and sufficient sample sizes for index analysis. Within each class, site characteristics could be discerned (Appendix D). However, it was necessary to lump wetlands of

similar metric characteristics to evaluate metric discrimination across disturbance types in relatively similar wetland settings.

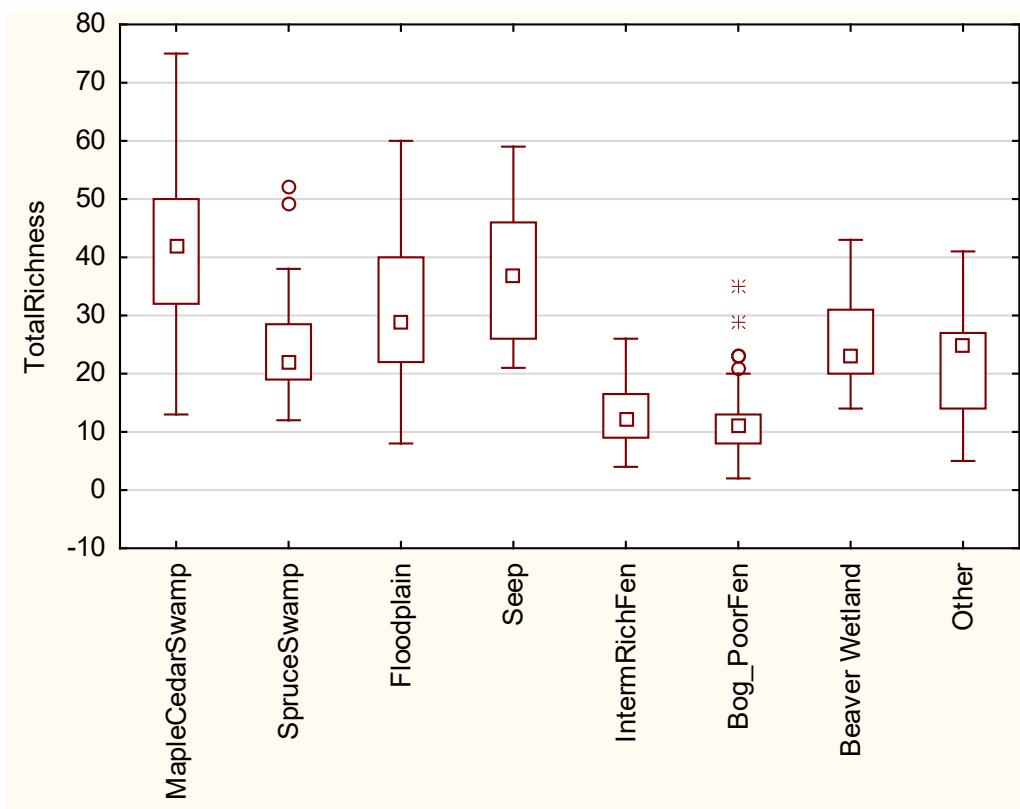

Figure 8. Distributions of total plant richness per wetland by preliminary wetland grouping.

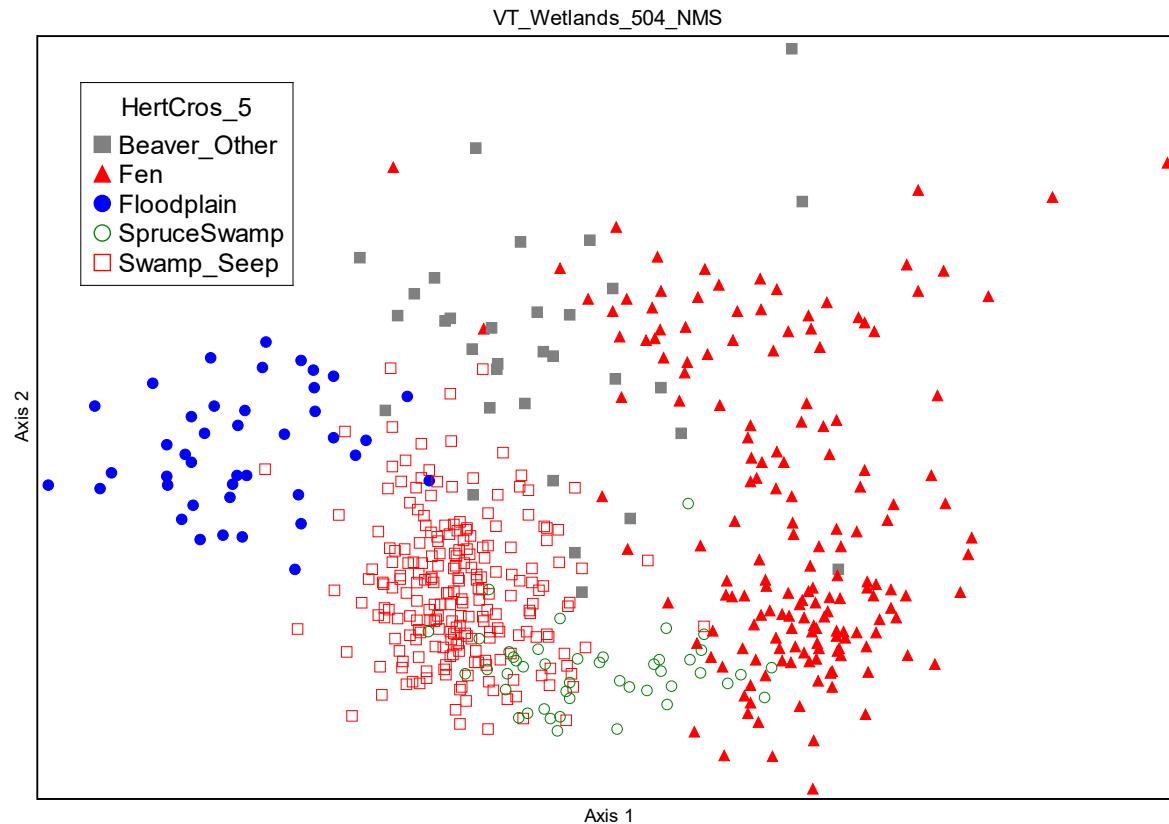

Figure 9. NMS diagram of reference wetland plant communities in final/proposed wetland classes.

Metric Discrimination of Disturbance

Based on visual inspection of box plots, many metrics discriminate reference and stressed sites in the selected survey types and all wetland types (Appendix C). Metric Discrimination Efficiency (DE) is the percentage of stressed sites that are outside the intraquartile reference distribution in one direction (% lower than the 25th percentile or % higher than the 75th percentile). We calculated DE and trend with disturbance for all sites and for each site class (Table 6). There were few stressed sites in the Fens and the Swamp/Seep wetland types. There were no stressed sites Spruce Swamp type. With few or no samples, discrimination results for metrics in these types are not robust indications.

There were 15 metrics that consistently decreased with increasing stress (DE >50%) in all wetland types (except the fens). In addition, there were two metrics that increased consistently, including the % cover of native monocotyledons. The sensitive metrics were all calculated based on native status and the CoC trait. Three metrics with especially strong signals relative to disturbance are the percent cover of native species, the relative importance of native species, and the weighted average of species CoC values. Existing wetland plant indices (weighted FQI, FQI, FQAI, and VMMI) are sensitive to disturbance, but not consistently over the site types. Only the weighted FQI was responsive in all wetland types, but the DE was lower overall and in the Beaver/Other type compared to the unweighted FQI and the FQAI.

Table 6. Discrimination efficiency (DE) and trend with increasing stress for wetland plant metrics in all VT wetlands and by wetland type.

Possible Assessment Considerations

Two metrics discriminate well separately (Figure 10), represent different aspects of the plant community (native status and tolerance), and could be combined in a new multimetric index. The Relative Importance of Native species (RelImpNative) represents both richness and abundance of native species. It is sensitive to the disturbance gradient except in the Fens, which are only evaluated using two stressed sites. It is also unassessed in the Spruce Swamps, which do not have any stressed examples. The weighted average of species CoC values metric (wat_tolerance [weighted average by taxa]) is sensitive in all wetland types, though the DE is only moderately high in the Floodplains.

When these two metrics are converted to a common scale and averaged together as a preliminary VT DEC Index, they outperform all individual metrics or indices when considered in all wetland types (Table 7). This index cannot be test in the Spruce Swamp wetland type.

Table 7. Metric and new VT DEC index discrimination efficiency over all sites and by wetland type. "NR" = not responsive.

Metric	ALL TYPES	Beaver_Other	Fen	Floodplain	Swamp_Seep
	DE	DE	DE	DE	DE
RelImpNative	92.9	92.3	NR	90.9	100
wat_tolerance	97.6	84.6	100	54.5	100
VT DEC Index	95.2	92.3	100	81.8	100

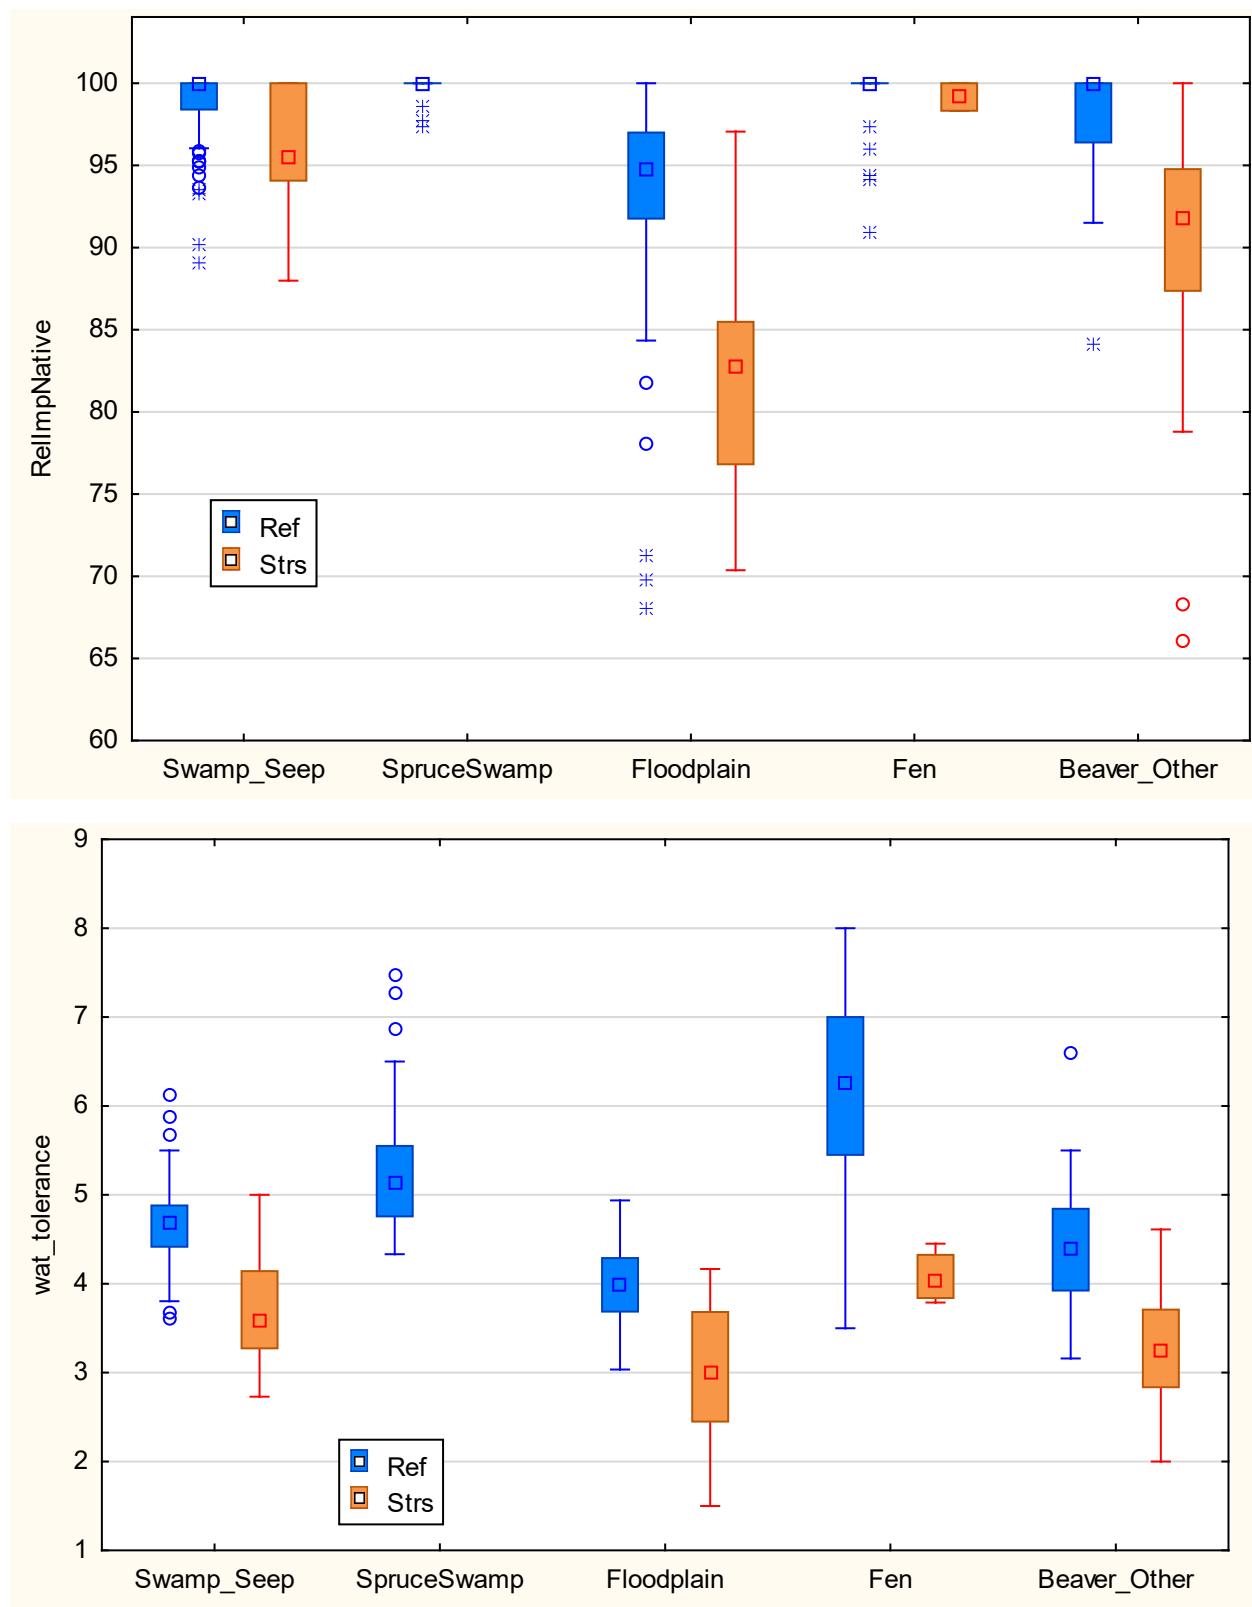

Figure 10. Index metric distributions in disturbance categories and site classes.

Index application

Scoring

Metrics are scored based on the following formulae:

Table 8. Metric scoring formulae for the proposed two-metric wetland index.

Metric	Metric Scoring Formula
RellImpNative	$100 * (\text{RellImpNative} - 89.4) / (100 - 89.4)$
wat_tolerance	$100 * (\text{wat_tolerance} - 3.3) / (7.1 - 3.3)$

For all calculations, scores that exceed 100 or are less than 0 are re-set to 100 or 0 (respectively) before averaging in the index. The index is calculated by averaging the metric scores.

Index Distributions

The index discriminates in all wetland types in which there are stressed sites for evaluation. The reference index expectations vary by wetland type (Figure 11).

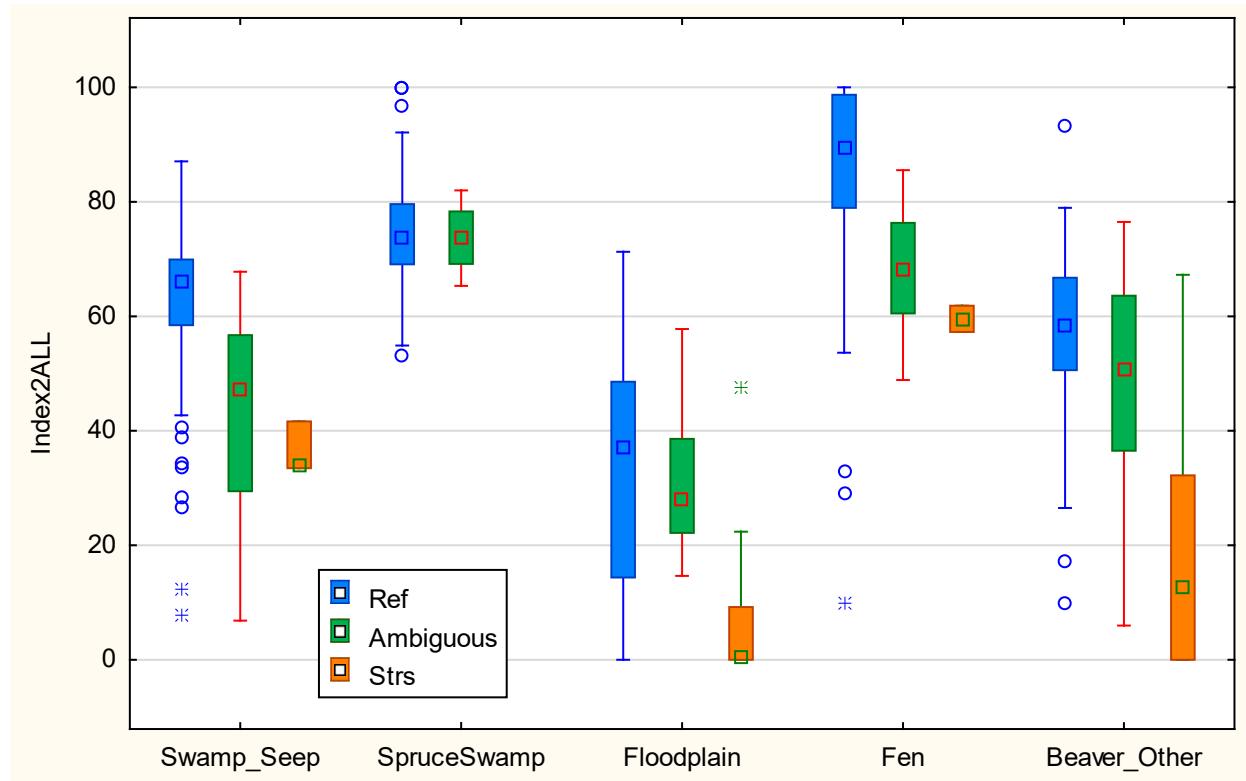

Figure 11. Index value distributions among site classes and disturbance categories for the proposed two-metric wetland index.

Assessment Thresholds

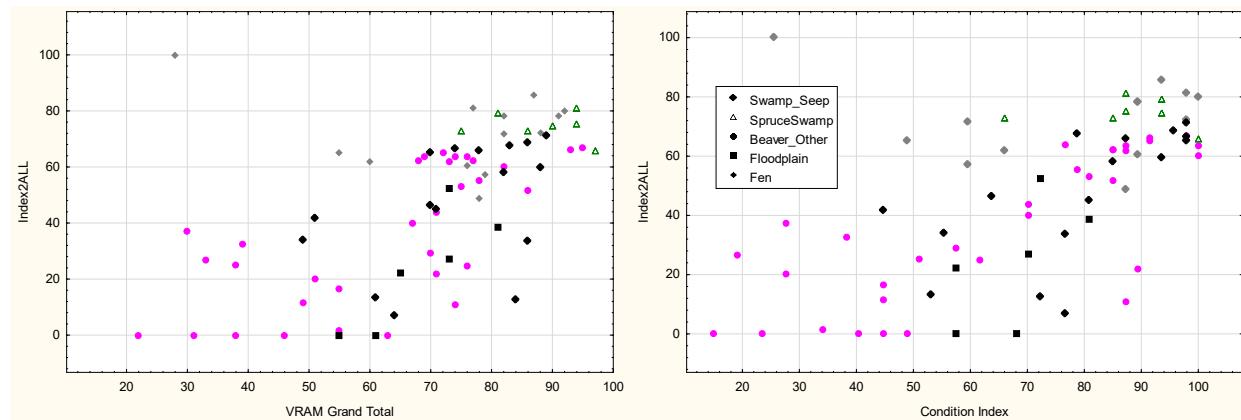

No assessment thresholds for designating impairment are recommended based on these analyses. However, if the VT DEC decides to assign narrative descriptions of wetland condition based on the site type and index, then the following (Table 9) might be appropriate. These are generally derived from the reference index distributions values at the reference median and lower quartile, and the upper quartile of stressed index scores. Results of metrics and the index for each wetland sample are displayed in Appendix E.

Table 9. Possible ranges of index values corresponding to narrative conditions for each wetland class.

Narrative Condition	Swamp_Seep	SpruceSwamp	Floodplain	Fen	Beaver_Other
Excellent	> 65	> 75	> 35	> 90	> 60
Good	60 - 65	70 - 75	15 - 35	80 - 90	50 - 60
Fair	40 - 60	< 70	10 - 15	60 - 80	30 - 50
Poor	< 40	NA	<10	<60	<30

Relation to Stressors

The two-metric wetland index was related to some stressors, including the VRAM (total score, the condition index of the VRAM, conductivity, and chloride (Figure 12). Additional graphics showing relationships between the index and site conditions are shown in Appendix F.

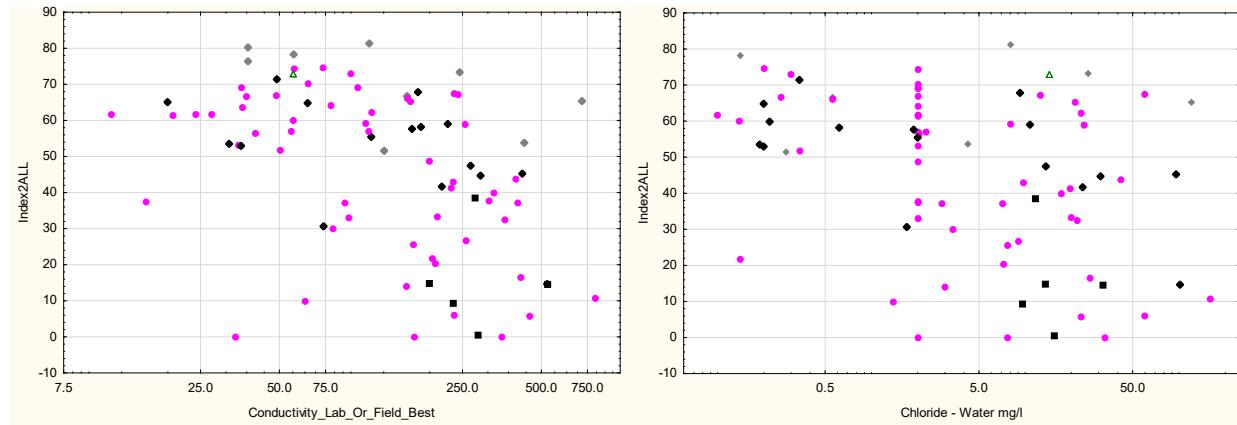

Figure 12. The proposed two-metric wetland index in relation to stressor variables, including the VRAM (total score, the condition index of the VRAM, conductivity, and chloride.

Data Gaps

The wetland monitoring emphasis in Vermont has been on specific targeted wetlands and on wetlands with relatively little disturbance. This is evident in the a priori disturbance categories assigned to sites for the current analysis. Most sites fell in to the “reference” or relatively undisturbed category. The emphasis serves the purposes of the monitoring programs, and allows recognition of wetland types in relatively natural settings. However, is not ideal for detecting wetland metric sensitivity to stressors because there are few stressed sites to show consistent changes in metric values across the disturbance gradient.

To continue evaluating metric responsiveness and to validate the index in future analyses, the gaps in the disturbance gradient should be filled with additional samples or sites. Specifically, wetland sites with substantial disturbance should be monitored. As shown in Table 10, there are very few stressed sites in three site classes: fens, spruce swamps, and swamp/seeps.

Table 10. Tally of samples by site class and disturbance category.

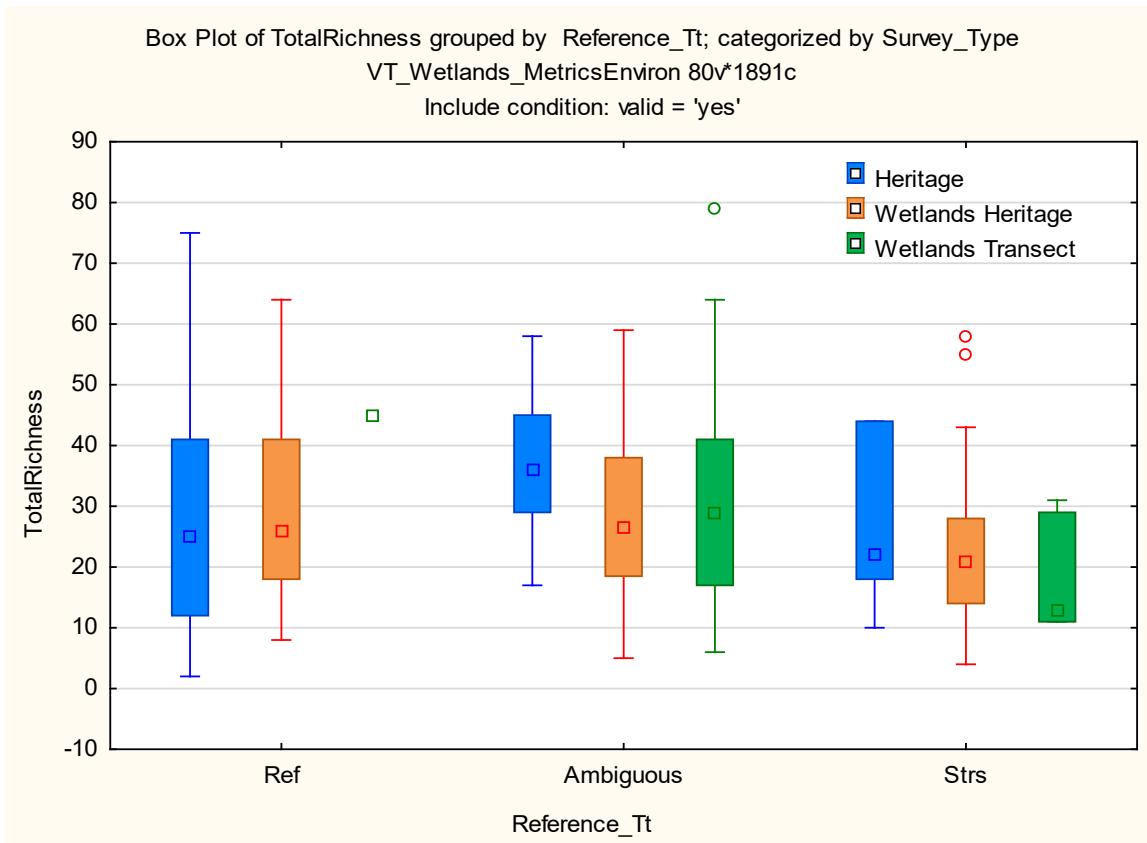

Site Class	Ref	Strs
Beaver_Other	29	26
Fen	166	2
Floodplain	41	11
SpruceSwamp	45	0
Swamp_Seep	222	3
All sites	503	42

Several wetland monitoring programs do not use methods or recording standards comparable to the Heritage, Wetlands Heritage, or Wetlands Transect programs. If feasible to implement consistent sampling among programs, it would allow for data pooling in future analyses.

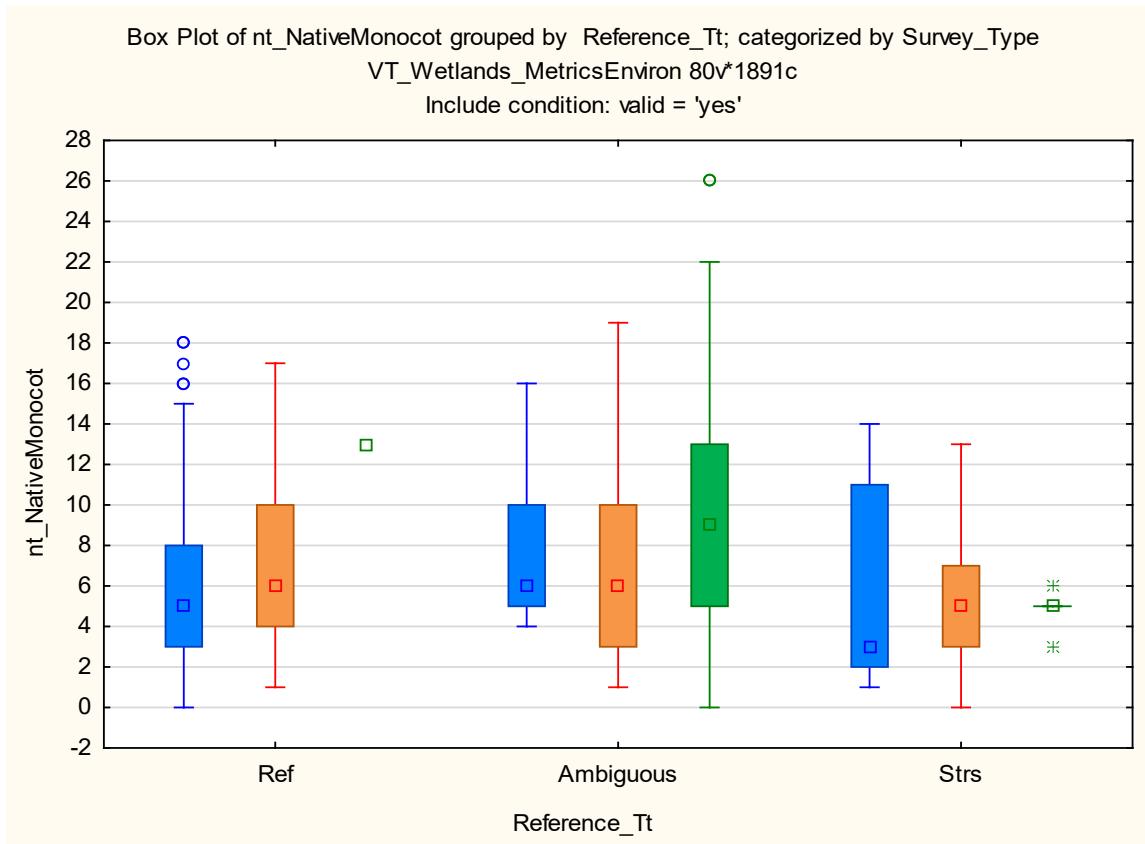

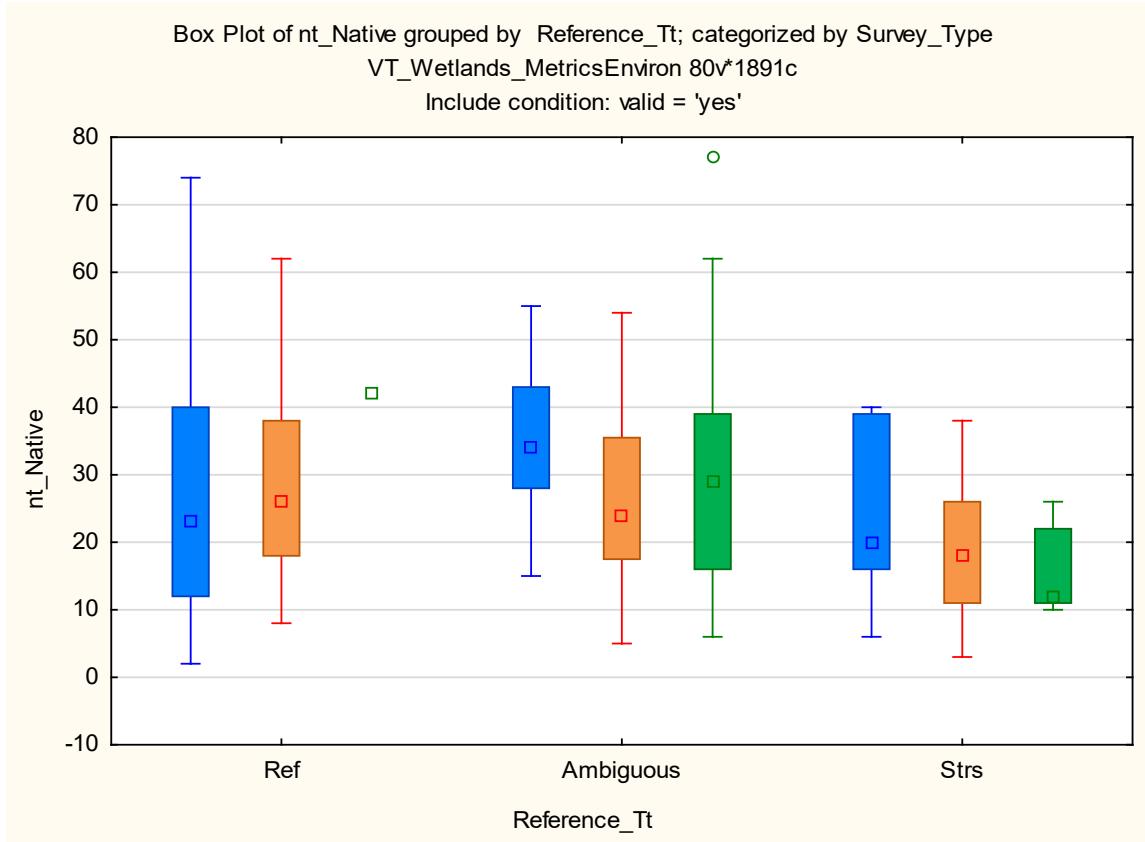

VT DEC has experimented with wetland plant trait assignments related to tolerances to stressors and to specific wetland conditions. The traits used for metric calculations in the current analyses were acceptable because they were traceable to precedents and publications. Confirmation or new assignment of traits would increase confidence in the existing metrics and would allow for calculation of metrics indicative of additional conditions.
